Practical Machine Learning - Final Project

Aleksa Lakic

21/05/2020

This document is my final project for the Coursera's "Practical Machine Learning" course. It was produced using R Markdown and the Knit functionality on Rstudio.

I - Overview of the project

1. Introduction

Using devices such as Jawbone Up, Nike FuelBand, and Fitbit it is now possible to collect a large amount of data about personal activity relatively inexpensively. These type of devices are part of the quantified self movement – a group of enthusiasts who take measurements about themselves regularly to improve their health, to find patterns in their behavior, or because they are tech geeks. One thing that people regularly do is quantify how much of a particular activity they do, but they rarely quantify how well they do it.

One thing that people regularly do is quantify how much of a particular activity they do, but they rarely quantify how well they do it. They were asked to perform barbell lifts correctly and incorrectly in 5 different ways.

2. Objective

In this project, our goal will be to use data from accelerometers on the belt, forearm, arm, and dumbell of 6 participants to predict the manner in which they did the exercise. This is the "classe" variable in the training set.

II - Methodology for the data collection and preparation

1. Preparation of the Environment

Installation/loading of the packages necessary for the project

The packages were installed by using the function install.packages("name of the library"). Example: install.packages("rpart").

The following libraries were used for this project:

library(caret)

- ## Loading required package: lattice
- ## Loading required package: ggplot2

```
library(e1071)
library(rattle)
## Rattle: A free graphical interface for data science with R.
## Version 5.3.0 Copyright (c) 2006-2018 Togaware Pty Ltd.
## Entrez 'rattle()' pour secouer, faire vibrer, et faire défiler vos données.
library(rpart)
library(rpart.plot)
library(RColorBrewer)
library(randomForest)
## randomForest 4.6-14
## Type rfNews() to see new features/changes/bug fixes.
## Attaching package: 'randomForest'
## The following object is masked from 'package:rattle':
##
##
       importance
## The following object is masked from 'package:ggplot2':
##
       margin
library(corrplot)
## corrplot 0.84 loaded
library(gbm)
## Loaded gbm 2.1.5
library(lattice)
library(ggplot2)
library(rmarkdown)
2. Data preparation
Download the data
```

```
# Upload the date from the internet
Training_URL <- "https://d396qusza40orc.cloudfront.net/predmachlearn/pml-training.csv"
Testing_URL <- "https://d396qusza40orc.cloudfront.net/predmachlearn/pml-testing.csv"
# Read the data on RStudio
Train_Raw_Data <- read.csv(url(Training_URL), header = TRUE)
Valid_Raw_Data <- read.csv(url(Testing_URL), header = TRUE)</pre>
```

Note: The datasets used in this project are available thanks to W. Ugilino, D. Cardador, K. Vega, E. Velloso, R. Milidiu, H. Fuks of their document called "Wearable Computing: Accelerometers' Data Classification of Body Postures and Movements".

```
#Show the data
str(Train_Raw_Data)
```

```
## 'data.frame':
                   19622 obs. of 160 variables:

     [list output truncated]
#The dimension of the two dataset
```

dim(Train_Raw_Data)

```
## [1] 19622 160
```

```
dim(Valid_Raw_Data)
```

[1] 20 160

- Both datasets have 160 variables
- Training dataset: 19622 Observations
- Validation dataset: 20 observations

The "Train Raw Data" dataset will be used as an input to create the dataset for the prediction models.

The dataset "Valid_Raw_Data" will be used to test the prediction model on the 20 test cases.

This partitioning will work for determining the out-of-sample errors.

3. Data Partitioning

We partitioned the training dataset called "pml-training.csv" into two datasets: * 70% for the training dataset * 30% for the testing dataset

```
set.seed(28765)
TrainingSample <- createDataPartition(Train_Raw_Data$classe, p = 0.7, list = FALSE)
Train_Set <- Train_Raw_Data[TrainingSample, ]
Test_Set <- Train_Raw_Data[-TrainingSample, ]
dim(Train_Set)</pre>
```

```
## [1] 13737 160
```

```
dim(Test_Set)
```

```
## [1] 5885 160
```

Both datasets have 160 variables. They includes many missing values and the first 7 columns have little impact on the variable "classe". Some columns have values close to 0. Thus, we need to clean and prepare the data.

3. Clean and prepare the data

Remove variables that contains missing values

```
#remove variables that contains missing values
Train_Set <- Train_Set[, colSums(is.na(Train_Set)) == 0]
Test_Set <- Test_Set[, colSums(is.na(Test_Set)) == 0]
#Dimension of both sets of data
dim(Train_Set)</pre>
```

```
## [1] 13737 93
```

```
dim(Test_Set)
```

Remove variables that would have little impact on the variable "classe"

```
#remove variables in the uploaded data of the training dataset
Train_Set <- Train_Set[, -c(1:7)]
dim(Train_Set)
## [1] 13737 86</pre>
```

```
#remove variables in the validation dataset
Test_Set <- Test_Set[, -c(1:7)]
dim(Test_Set)</pre>
```

```
## [1] 5885 86
```

[1] 5885

93

Cleaning by removing the variables that have a near zero variance

```
AZV <- nearZeroVar(Train_Set)
Train_Set <- Train_Set[, -AZV]
Test_Set <- Test_Set[, -AZV]
dim(Train_Set)

## [1] 13737 53

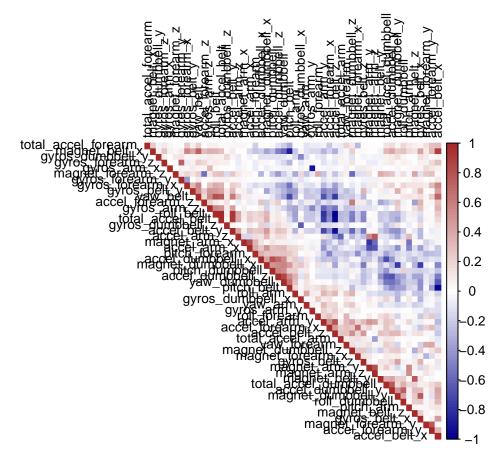

dim(Test_Set)</pre>
```

```
## [1] 5885 53
```

By doing these manipulations, we have 53 variables now. How are these variables correlated between them?

4. Correlation between variables

Compute the correlation between the different variables

In this graph, we observe the correlation between the different variables. Variables which have dark blue or dark brown intersections with others are the most correlated between them.

Find the names of the variables that are highly correlated

```
highCor = findCorrelation(corMatrix, cutoff = 0.8) # The 20% most correlated variables
names(Train_Set)[highCor] # Show the names of the highly correlated variables
```

III - Prediction Model Building

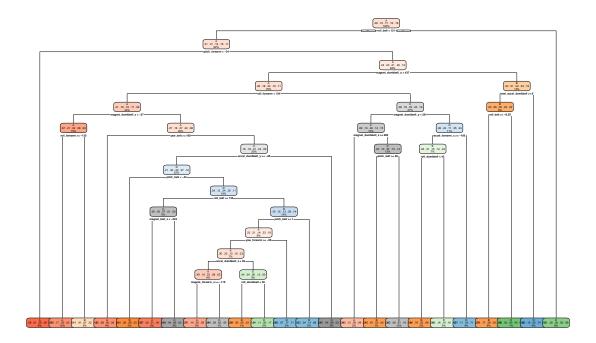

1. Classification trees' model (class)

Set the model"'

```
set.seed(28765)
ModelTree <- rpart(classe ~ ., data=Train_Set, method="class") #use of the rpart package
rpart.plot(ModelTree, main="Classfication Trees") #Plot the classification trees as a dendogram</pre>
```

Warning: labs do not fit even at cex 0.15, there may be some overplotting

Classfication Trees

Classification Trees' Prediction Model

B C

We use the model on the Test_Data and determine the accuracy of the model.

```
PredictClassTree <- predict(ModelTree, Test_Set, type = "class") #Predict function for this model

CMtree <- confusionMatrix(PredictClassTree, as.factor(Test_Set$classe)) #Create the matrix of the predi

CMtree # Show the matrix
```

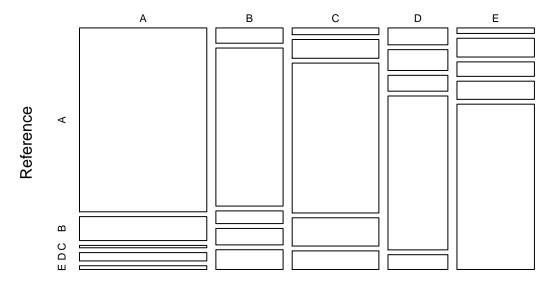

```

                                                                 0.9980
```

Plot the confusion matrix

Random Forest Model's Accuracy = 0.9918

- The accuracy rate of the model is very high: 0.9918
- The out-of-sample error is very low (around 0.008)

IV - Conclusion and final results

1. Choose the most accurate prediction model for the validation dataset

From the previous computations, we obtain the following results:

- Classification Tree Model's Accuracy = 0.7422
- G model's accuracy = 0.958
- Random Forest Model's Accuracy = 0.9918

As the Random Forest model is the most accurate for the prediction in-sample. Thus, we will use it to predict 20 different test cases.

2. Results

```
# The dataset "Valid_Raw_Data" contains the 20 test cases
predict_test <- predict(RF_Model , newdata=Valid_Raw_Data)</pre>
predict_test
```
